RFC 9899

Extensions to the YANG Data Model for Access Control Lists (ACLs)

Abstract

RFC 8519 defines a YANG data model for Access Control Lists (ACLs). This document specifies a set of extensions that fix many of the limitations of the ACL model as initially defined in RFC 8519. Specifically, it introduces augmentations to the ACL base model to enhance its functionality and applicability.

This document also defines initial versions of IANA-maintained modules for ICMP types and IPv6 extension headers.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 7841.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at <https://www.rfc-editor.org/info/rfc9899>.

1. Introduction

[RFC8519] defines Access Control Lists (ACLs) as a user-ordered set of filtering rules. The model targets the configuration of the filtering behavior of a device. However, the model structure, as defined in [RFC8519], suffers from a set of limitations. This document identifies these limitations and specifies an enhanced ACL structure, introducing augmentations to the ACL base model (Section 4). The motivation of such an enhanced ACL structure is discussed in detail in [Appendix A](#).

When managing ACLs, it is common for network operators to group match elements in predefined sets. The consolidation into group matches allows for reducing the number of rules, especially in large-scale networks. For example, if finding a match against 100 IP addresses (or

prefixes) is needed, a single rule will suffice rather than creating individual Access Control Entries (ACEs) for each IP address (or prefix). In doing so, implementations would optimize the performance of matching lists versus multiple rules matching.

The enhanced ACL structure (see "ietf-acl-enh" in [Section 4](#)) is also meant to facilitate the management of network operators. Instead of entering the IP address or port number literals, using user-named lists decouples the creation of the rule from the management of the sets. Hence, it is possible to remove/add entries to the list without redefining the (parent) ACL rule.

In addition, the notion of ACL and defined sets is generalized so that it is not device specific as per [\[RFC8519\]](#). ACLs and defined sets may be defined at the network/administrative domain level and associated to devices. This approach facilitates the reusability across multiple network elements. For example, managing the IP prefix sets from a network level makes it easier to maintain by the security groups.

Network operators maintain sets of IP prefixes that are related to each other, e.g., deny-lists or accept-lists that are associated with those provided by a VPN customer. These lists are maintained and manipulated by security expert teams of the network operators.

Note that ACLs are used locally in devices but are triggered by other tools such as DDoS mitigation [\[RFC9132\]](#) or BGP Flow Spec [\[RFC8955\]](#) [\[RFC8956\]](#). Therefore, it is valuable from a network operation standpoint to support the means to easily map to the filtering rules conveyed in messages triggered by these tools.

The enhanced ACL module ([Section 4](#)) conforms to the Network Management Datastore Architecture (NMDA) defined in [\[RFC8342\]](#).

A set of examples to illustrate the use of the enhanced ACL module is provided in [Appendix B](#).

This document also defines initial versions of IANA-maintained modules for ICMP types and IPv6 extension headers. The design of the modules adheres to the recommendations in [Section 4.30.2](#) of [\[YANG-GUIDELINES\]](#). The latest version of these IANA-maintained modules can be retrieved from the "YANG Parameters" registry group [\[IANA-YANG-PARAMETERS\]](#).

2. Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [\[RFC2119\]](#) [\[RFC8174\]](#) when, and only when, they appear in all capitals, as shown here.

The terminology for describing YANG modules is defined in [\[RFC7950\]](#). The meaning of the symbols in the tree diagrams is defined in [\[RFC8340\]](#).

In addition to the terms defined in [\[RFC8519\]](#), this document makes use of the following term:

Defined set:

Elements in a defined set typically share a logical purpose or function, such as IP addresses, IP prefixes, port numbers, or ICMP types.

3. Overall Structure of the Enhanced ACL Module

3.1. Tree Structure

[Figure 1](#) shows the full tree of the enhanced ACL module ([Section 4](#)):

Figure 2: Enhanced ACL Groupings

3.2. Defined Sets

The augmented ACL structure includes several containers to manage reusable sets of elements that can be matched in an ACL entry. Each set is uniquely identified by a name and can be called from the relevant entry. The following sets (seen in [Figure 1](#)) are defined:

IPv4 prefix sets: An IPv4 prefix set contains a list of IPv4 prefixes. A match will be considered if the IP address (source or destination, depending on the ACL entry) is contained in any of the prefixes in the set.

IPv6 prefix sets: An IPv6 prefix contains a list of IPv6 prefixes. A match will be considered if the IP address (source or destination, depending on the ACL entry) is contained in any of the prefixes in the set.

Port sets: A port set contains a list of port numbers to be used in transport protocol entries (e.g., TCP and UDP).

A port number can be a port range or a single port number along with an operator (equal to, greater than or equal to, etc.).

Protocol sets: A protocol set contains a list of protocol values. A protocol can be identified by either a number (e.g., 17) or a name (e.g., UDP).

ICMP sets: An ICMP set contains a list of ICMPv4 [[RFC0792](#)] or ICMPv6 [[RFC4443](#)] types, and each type is identified by a type value and is optionally identified by the code and the rest of the header.

IANA-maintained modules for ICMP types are defined in this document.

Aliases: An alias is defined by a combination of various parameters (e.g., IP prefix, protocol, port number, or VLAN [[IEEE802.1Qcp](#)]). When only sets of one parameter (e.g., protocol) are handled, then the relevant parameter sets should be used (e.g., protocol set) rather than an alias.

For example, an alias can be defined to apply ACL policies bound to a set of HTTPS servers. Such an alias will typically include these HTTPS server addresses (e.g., "prefix": ["2001:db8:6401::1/128", "2001:db8:6401::2/128"]) and the TCP port number 443 (i.e., "protocol": [6] and "lower-port": 443).

Sets of aliases can be defined and referred to in ACL match criteria.

Payload-based filtering: A network traffic filtering technique that examines the data payload of packets, beyond just the header information, to identify, allow, or block traffic based on specific content or patterns within the payload. An offset type (e.g., Layer 2 or Layer 3) is used to indicate the position of the data in the packet to use for the match.

3.3. IPv6 Extension Headers

The enhanced ACL module can be used to manage ACLs that require matching against IPv6 extension headers [[RFC8200](#)]. To that aim, a new IANA-maintained module for IPv6 extension header types, "iana-ipv6-ext-types", is defined in this document.

3.4. TCP Flags Handling

The augmented ACL module includes a new container 'flags-bitmask' to better handle TCP flags (Section 3.1 of [[RFC9293](#)]). Assigned TCP flags are maintained in the "TCP Header Flags" registry under the "Transmission Control Protocol (TCP) Parameters" registry group [[IANA-TCP-FLAGS](#)].

Clients that support both 'flags-bitmask' and 'flags' [RFC8519] matching fields **MUST NOT** set these fields in the same request.

3.5. Fragments Handling

The augmented ACL module includes new leafs 'ipv4-fragment' and 'ipv6-fragment' to better handle fragments.

Clients that support both 'ipv4-fragment' and 'flags' [RFC8519] matching fields **MUST NOT** set these fields in the same request.

3.6. Payload-Based Filtering

Some transport protocols use existing protocols (e.g., TCP or UDP) as substrate. The match criteria for such protocols may rely upon the 'protocol' under 'l3', TCP/UDP match criteria, part of the TCP/UDP payload, or a combination thereof.

A new feature, called 'match-on-payload', is defined in the document. This can be used, for example, for QUIC [RFC9000] or for tunneling protocols. This feature requires configuring a data offset, a length, and a binary pattern to match data against using a specified operator. The data offset indicates the position to look at in a packet (e.g., it starts at the beginning of the IP header or transport header).

3.7. Match on MPLS Headers

The enhanced ACL module (Section 4) can be used to create rules to match against the MPLS fields of a packet. The MPLS header defined in [RFC3032] and [RFC5462] contains the following fields:

- Traffic Class: The 3-bit "Exp" field [RFC3032], which is renamed to "Traffic Class field" ("TC field") [RFC5462].
- Label Value: A 20-bit field that carries the actual value of the MPLS label.
- TTL: An 8-bit field used to encode the Time-to-Live (TTL) value.

The augmented ACL module can be used by an operator to configure ACLs that match based upon the following data nodes:

- 'traffic-class'
- 'label-position' (e.g., top or bottom)
- 'upper-label-range'
- 'lower-label-range'
- 'label-block-name'
- 'ttl-value'

3.8. VLAN Filtering

Being able to filter all packets that are bridged within a VLAN or that are routed into or out of a bridge domain is part of the VPN control requirements for Ethernet VPN (EVPN) [RFC7209].

All packets that are bridged within a VLAN or that are routed into or out of a VLAN can be captured, forwarded, translated, or discarded based on the network policy.

3.9. Instance Service Identifier (I-SID) Filtering

Provider Backbone Bridging (PBB) was originally defined as a Virtual Bridged Local Area Networks standard [IEEE-802-1ah]. However, instead of multiplexing VLANs, PBB duplicates the Media Access Control (MAC) layer of the customer frame and separates it from the provider domain, by encapsulating it in a 24-bit Instance Service Identifier (I-SID). This provides more transparency between the customer network and the provider network.

The I-component forms the customer- or access-facing interface or routing instance. The I-component is responsible for mapping customer Ethernet traffic to the appropriate I-SID. It is mandatory to configure the default service identifier in the network.

Being able to filter by I-component service identifier is a feature of the EVPN-PBB configuration.

3.10. Additional Actions

In order to support rate-limiting (see [Appendix A.6](#)), a new action called 'rate-limit' is defined in this document.

Also, the "ietf-acl-enh" module supports new actions to complement existing ones: log ('log-action') and write a counter ('counter-action'). The version of the module defined in this document supports only local actions.

4. Enhanced ACL YANG Module

This YANG module imports types from [RFC6991], [RFC8519], and [RFC8294].

```
<CODE BEGINS> file "ietf-acl-enh@2025-11-07.yang"

5. Security Considerations

This section is modeled after the template described in [Section 3.7.1](#) of [\[YANG-GUIDELINES\]](#).

The "ietf-acl-enh" YANG module defines a data model that is designed to be accessed via YANG-based management protocols, such as NETCONF [\[RFC6241\]](#) and RESTCONF [\[RFC8040\]](#). These YANG-based management protocols (1) have to use a secure transport layer (e.g., SSH [\[RFC4252\]](#), TLS [\[RFC8446\]](#), and QUIC [\[RFC9000\]](#)) and (2) have to use mutual authentication.

The Network Configuration Access Control Model (NACM) [\[RFC8341\]](#) provides the means to restrict access for particular NETCONF or RESTCONF users to a preconfigured subset of all available NETCONF or RESTCONF protocol operations and content.

There are a number of data nodes defined in this YANG module that are writable/creatable/deletable (i.e., "config true", which is the default). All writable data nodes are likely to be reasonably sensitive or vulnerable in some network environments. Write operations (e.g., edit-config) and delete operations to these data nodes without proper protection or authentication can have a negative effect on network operations. The following subtrees and data nodes have particular sensitivities/vulnerabilities:

'defined-sets': These lists specify a set of IP addresses, port numbers, protocols, ICMP types, and aliases. Similar to [\[RFC8519\]](#), unauthorized write access to these lists can allow intruders to modify the entries to permit traffic that should not be permitted or deny traffic that should be permitted. The former may result in a DoS attack or compromise a device. The latter may result in a DoS attack.

These sets are defined with "nacm:default-deny-write" tagging.

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. Specifically, the following subtrees and data nodes have particular sensitivities/vulnerabilities:

'defined-sets':

Unauthorized read access of these lists will allow an attacker to identify the actual resources that are bound to ACLs. Likewise, access to this information will help an attacker to better scope its attacks to target resources that are specific to a given network instead of performing random scans. Also, disclosing some of this information (e.g., IP addresses of core routers) may nullify the effect of topology-hiding strategies in some networks.

There are no particularly sensitive RPC or action operations.

The document defines a match policy based on a pattern that can be observed in a packet. For example, such a policy can be combined with header-based matches in the context of DDoS mitigation. Filtering based on a pattern match is deterministic for packets with unencrypted data. However, the efficiency for encrypted packets depends on the presence of an unvarying pattern. Readers may also refer to [Section 11](#) of [\[RFC8329\]](#) for security considerations related to Network Security Functions (NSFs) that apply packet content matching.

The YANG modules "iana-icmpv4-types", "iana-icmpv6-types", and "iana-ipv6-ext-types" define a set of types. These nodes are intended to be reused by other YANG modules. Each module by itself does not expose any data nodes that are writable, data nodes that contain read-only state, or RPCs. As such, there are no additional security issues related to these YANG modules that need to be considered.

6. IANA Considerations

6.1. URI Registrations

IANA has registered the following URIs in the "ns" registry within the "IETF XML Registry" [\[RFC3688\]](#):

URI: urn:ietf:params:xml:ns:yang:ietf-acl-enh
Registrant Contact: The IESG
XML: N/A; the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:iana-icmpv4-types
Registrant Contact: The IESG
XML: N/A; the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:iana-icmpv6-types
Registrant Contact: The IESG
XML: N/A; the requested URI is an XML namespace.

URI: urn:ietf:params:xml:ns:yang:iana-ipv6-ext-types
Registrant Contact: The IESG
XML: N/A; the requested URI is an XML namespace.

6.2. YANG Module Name Registrations

IANA has registered the following YANG modules in the "YANG Module Names" registry [[RFC6020](#)] [[RFC9890](#)] within the "YANG Parameters" registry group.

Name: ietf-acl-enh
Maintained by IANA: N
Namespace: urn:ietf:params:xml:ns:yang:ietf-acl-enh
Prefix: acl-enh
Reference: RFC 9899

Name: iana-icmpv4-types
Maintained by IANA: Y
Namespace: urn:ietf:params:xml:ns:yang:iana-icmpv4-types
Prefix: iana-icmpv4-types
Reference: RFC 9899

Name: iana-icmpv6-types
Maintained by IANA: Y
Namespace: urn:ietf:params:xml:ns:yang:iana-icmpv6-types
Prefix: iana-icmpv6-types
Reference: RFC 9899

Name: iana-ipv6-ext-types
Maintained by IANA: Y
Namespace: urn:ietf:params:xml:ns:yang:iana-ipv6-ext-types
Prefix: iana-ipv6-ext-types
Reference: RFC 9899

6.3. Considerations for IANA-Maintained Modules

6.3.1. ICMPv4 Types IANA Module

This document defines the initial version of the IANA-maintained "iana-icmpv4-types" YANG module. The most recent version of the YANG module is available in the "YANG Parameters" registry group [[IANA-YANG-PARAMETERS](#)].

IANA has added this note to the registry:

New values must not be directly added to the "iana-icmpv4-types" YANG module. They must instead be added to the "ICMP Type Numbers" registry [[IANA-ICMPv4](#)].

When a value is added to the "ICMP Type Numbers" registry, a new "enum" statement must be added to the "iana-icmpv4-types" YANG module. The "enum" statement, and substatements thereof, should be defined as follows:

"enum": Replicates the name from the registry with all illegal characters (e.g., spaces) stripped.

"value": Contains the decimal value of the IANA-assigned value.

"status": Included only if a registration has been deprecated or obsoleted. IANA "deprecated" maps to YANG status "deprecated", and IANA "obsolete" maps to YANG status "obsolete".

"description": Replicates the name from the registry.

"reference": Replicates the reference(s) from the registry with the title of the document(s) added.

Unassigned, reserved, or values styled like those in [\[RFC3692\]](#) are not present in the module.

When the "iana-icmpv4-types" YANG module is updated, a new "revision" statement with a unique revision date must be added in front of the existing revision statements.

IANA has added this note to "ICMP Type Numbers" registry [\[IANA-ICMPv4\]](#) and listed this document as an additional reference for the registry:

When this registry is modified, the YANG module "iana-icmpv4-types" [\[IANA-YANG-PARAMETERS\]](#) must be updated as defined in RFC 9899.

6.3.2. ICMPv6 Types IANA Module

This document defines the initial version of the IANA-maintained "iana-icmpv6-types" YANG module. The most recent version of the YANG module is available in the "YANG Parameters" registry group [\[IANA-YANG-PARAMETERS\]](#).

IANA has added this note to the registry:

New values must not be directly added to the "iana-icmpv6-types" YANG module. They must instead be added to the "ICMPv6 "type" Numbers" registry [\[IANA-ICMPv6\]](#).

When a value is added to the "ICMPv6 "type" Numbers" registry, a new "enum" statement must be added to the "iana-icmpv6-types" YANG module. The "enum" statement, and substatements thereof, should be defined as follows:

"enum": Replicates the name from the registry with all illegal characters (e.g., spaces) stripped.

"value": Contains the decimal value of the IANA-assigned value.

"status": Included only if a registration has been deprecated or obsoleted. IANA "deprecated" maps to YANG status "deprecated", and IANA "obsolete" maps to YANG status "obsolete".

"description": Replicates the name from the registry.

"reference": Replicates the reference(s) from the registry with the title of the document(s) added.

Unassigned, reserved, or private experimentation values are not present in the module.

When the "iana-icmpv6-types" YANG module is updated, a new "revision" statement with a unique revision date must be added in front of the existing revision statements.

IANA has added this note to the "ICMPv6 "type" Numbers" registry [[IANA-ICMPv6](#)] and listed this document as an additional reference for the registry:

When this registry is modified, the YANG module "iana-icmpv6-types" [[IANA-YANG-PARAMETERS](#)] must be updated as defined in RFC 9899.

6.3.3. IPv6 Extension Header Types IANA Module

This document defines the initial version of the IANA-maintained "iana-ipv6-ext-types" YANG module. The most recent version of the YANG module is available in the "YANG Parameters" registry group [[IANA-YANG-PARAMETERS](#)].

IANA has added this note to the registry:

New values must not be directly added to the "iana-ipv6-ext-types" YANG module. They must instead be added to the "IPv6 Extension Header Types" registry [[IANA-IPv6](#)].

When a value is added to the "IPv6 Extension Header Types" registry, a new "enum" statement must be added to the "iana-ipv6-ext-types" YANG module. The "enum" statement, and substatements thereof, should be defined as follows

"enum": Replicates the description from the registry with all spaces stripped.

"value": Contains the decimal value of the IANA-assigned value.

"status": Included only if a registration has been deprecated or obsoleted. IANA "deprecated" maps to YANG status "deprecated", and IANA "obsolete" maps to YANG status "obsolete".

"description": Replicates the description from the registry.

"reference": Replicates the reference(s) from the registry with the title of the document(s) added.

Unassigned or reserved values are not present in the module.

When the "iana-ipv6-ext-types" YANG module is updated, a new "revision" statement with a unique revision date must be added in front of the existing revision statements.

IANA has added this note to the "IPv6 Extension Header Types" registry [IANA-IPv6] and listed this document as an additional reference for the registry:

When this registry is modified, the YANG module "iana-ipv6-ext-types" [IANA-YANG-PARAMETERS] must be updated as defined in RFC 9899.

Appendix A. Problem Statement and Gap Analysis

A.1. Suboptimal Configuration: Lack of Support for Lists of Prefixes

IP prefix-related data nodes (e.g., "destination-ipv4-network" or "destination-ipv6-network") do not support handling a list of IP prefixes, which may then lead to having to support large numbers of ACL entries in a configuration file.

The same issue is encountered when ACLs have to be in place to mitigate DDoS attacks that involve a set of sources (e.g., [RFC9132]). The situation is even worse when both a list of sources and destination prefixes are involved in the filtering.

[Figure 3](#) shows an example of the required ACL configuration for filtering traffic from two prefixes.

```

{
  "ietf-access-control-list:acls": {
    "acl": [
      {
        "name": "first-prefix",
        "type": "ipv6-acl-type",
        "aces": {
          "ace": [
            {
              "name": "my-test-ace",

]
}
}
```

Figure 3: Example Illustrating Suboptimal Use of the ACL Model with a Prefix List (Message Body)

Such a configuration is suboptimal for both:

- network controllers that need to manipulate large files, as all or a subset for this configuration will need to be passed to the underlying network devices, and
- devices that may receive such a configuration and thus will need to maintain it locally.

A.2. Manageability: Impossibility of Using Aliases or Defined Sets

The same approach as the one discussed for IP prefixes can be generalized by introducing the concept of "aliases" or "defined sets".

The defined sets are reusable definitions across several ACLs. Each category is modeled in YANG as a list of parameters related to the class it represents. The following sets can be considered:

Prefix sets: Used to create lists of IPv4 or IPv6 prefixes.

Protocol sets: Used to create a list of protocols.

Port number sets: Used to create lists of TCP or UDP port values (or any other transport protocol that makes uses of port numbers). The identity of the protocols is identified by the protocol set, if present. Otherwise, a set applies to any protocol.

ICMP sets: Used to create lists of ICMP-based filters. This applies only when the protocol is set to ICMP or ICMPv6.

Aliases may also be considered to manage resources that are identified by a combination of various parameters (e.g., prefix, protocol, port number, FQDN, or VLAN IDs). Note that some aliases can be provided by decomposing them into separate sets.

A.3. Bind ACLs to Devices, Not Only Interfaces

In the context of network management, an ACL may be enforced in many network locations. As such, the ACL module should allow for binding an ACL to multiple devices, not only (abstract) interfaces.

Thus, the ACL name must be unique at the scale of the network, but the same name may be used in many devices when enforcing node-specific ACLs.

A.4. Partial or Lack of IPv4/IPv6 Fragment Handling

[RFC8519] does not support fragment handling for IPv6 but offers a partial support for IPv4 through the use of 'flags'. Nevertheless, the use of 'flags' is problematic since it does not allow a bitmask to be defined. For example, setting other bits not covered by the 'flags' filtering clause in a packet will allow that packet to get through (because it won't match the ACE).

Defining a new IPv4/IPv6 matching field called 'fragment' is thus required to efficiently handle fragment-related filtering rules.

A.5. Suboptimal TCP Flags Handling

[RFC8519] supports including flags in the TCP match fields; however, that structure does not support matching operations as those supported in BGP Flow Spec. Defining this field as a flag bitmask together with a set of operations is meant to efficiently handle TCP flags filtering rules.

A.6. Rate-Limit Action

[RFC8519] specifies that forwarding actions can be 'accept' (i.e., accept matching traffic), 'drop' (i.e., drop matching traffic without sending any ICMP error message), or 'reject' (i.e., drop matching traffic and send an ICMP error message to the source). However, there are situations where the matching traffic can be accepted, but with a rate-limit policy. This capability is not supported by [RFC8519].

A.7. Payload-Based Filtering

Some transport protocols use existing protocols (e.g., TCP or UDP) as substrate. The match criteria for such protocols may rely upon the 'protocol' under 'l3', TCP/UDP match criteria, part of the TCP/UDP payload, or a combination thereof. [RFC8519] does not support matching based on the payload.

Likewise, the ACL model defined in [RFC8519] does not support filtering of encapsulated traffic.

A.8. Reuse the Content of ACLs Across Several Devices

Having a global network view of the ACLs is highly valuable for service providers. An ACL could be defined and applied based on the network topology hierarchy. Therefore, an ACL can be defined at the network level, and then that same ACL can be used in (or referenced to) several devices (including termination points) within the same network.

This network/device differentiation of ACLs introduces several new requirements, for example:

- An ACL name can be used at both network and device levels.
- An ACL content updated at the network level should imply a transaction that updates the relevant content in all the nodes using this ACL.
- ACLs defined at the device level have a local meaning for the specific node.
- A device can be associated with a router, a Virtual Routing and Forwarding (VRF), a logical system, or a virtual node. ACLs can be applied in physical and logical infrastructure.

A.9. Match MPLS Headers

The ACLs can be used to create rules to match MPLS fields on a packet. [\[RFC8519\]](#) does not support such function.

Appendix B. Examples

This section provides a few examples to illustrate the use of the enhanced ACL module ("ietf-acl-enh").

B.1. TCP Flags Handling

[Figure 4](#) shows an example of the message body of a request to install a filter to discard incoming TCP messages having all flags unset.

```
{
  "ietf-access-control-list:acls": {
    "acl": [
      {
        "name": "tcp-flags-example",
        "aces": {
          "ace": [
            {
              "name": "null-attack",
              "matches": {
                "tcp": {
                  "ietf-acl-enh:flags-bitmask": {
                    "operator": "not any",
                    "bitmask": 4095
                  }
                }
              },
              "actions": {
                "forwarding": "drop"
              }
            }
          ]
        }
      }
    ]
  }
}
```

Figure 4: Example of an ACL to Deny TCP Null Attack Messages (Request Body)

B.2. Fragments Handling

Figure 5 shows the content of a POST request to allow the traffic destined to 198.51.100.0/24 and UDP port number 53, but to drop all fragmented packets. The following ACEs are defined (in this order):

"drop-all-fragments" ACE: discards all fragments.

"allow-dns-packets" ACE: accepts DNS packets destined to 198.51.100.0/24.

```

{
  "ietf-access-control-list:acls": {
    "acl": [
      {
        "name": "dns-fragments",
        "type": "ipv4-acl-type",
        "aces": {
          "ace": [
            {
              "name": "drop-all-fragments",
              "matches": {
                "ipv4": {
                  "ietf-acl-enh:ipv4-fragment": {
                    "operator": "match",
                    "type": "isf"
                  }
                }
              },
              "actions": {
                "forwarding": "drop"
              }
            },
            {
              "name": "allow-dns-packets",
              "matches": {
                "ipv4": {
                  "destination-ipv4-network": "198.51.100.0/24"
                },
                "udp": {
                  "destination-port": {
                    "operator": "eq",
                    "port": 53
                  }
                }
              },
              "actions": {
                "forwarding": "accept"
              }
            }
          ]
        }
      }
    ]
  }
}

```

Figure 5: Example Illustrating Candidate Filtering of IPv4 Fragmented Packets (Message Body)

Figure 6 shows an example of the body of a POST request to allow the traffic destined to 2001:db8::/32 and UDP port number 53, but to drop all fragmented packets. The following ACEs are defined (in this order):

"drop-all-fragments" ACE: discards all fragments (including atomic fragments). That is, IPv6 packets that include a Fragment header (44) are dropped.

"allow-dns-packets" ACE: accepts DNS packets destined to 2001:db8::/32.

```
{
  "ietf-access-control-list:acls": {
    "acl": [
      {
        "name": "dns-fragments",
        "type": "ipv6-acl-type",
        "aces": {
          "ace": [
            {
              "name": "drop-all-fragments",
              "matches": {
                "ipv6": {
                  "ietf-acl-enh:ipv6-fragment": {
                    "operator": "match",
                    "type": "isf"
                  }
                }
              },
              "actions": {
                "forwarding": "drop"
              }
            },
            {
              "name": "allow-dns-packets",
              "matches": {
                "ipv6": {
                  "destination-ipv6-network": "2001:db8::/32"
                },
                "udp": {
                  "destination-port": {
                    "operator": "eq",
                    "port": 53
                  }
                }
              },
              "actions": {
                "forwarding": "accept"
              }
            }
          ]
        }
      }
    ]
  }
}
```

Figure 6: An Example Illustrating Filtering of IPv6 Fragmented Packets (Message Body)

B.3. Pattern-Based Filtering

Pattern-based filtering is useful to detect specific patterns, signatures, or encapsulated packets. [Figure 7](#) shows an example of the message body of a request to install a filter to discard IP-in-IP encapsulated messages with an inner destination IP address equal to "2001:db8::1". By using the offset at the end of Layer 3, the rule targets a specific portion of the payload that starts 20 bytes after the beginning of the data (that is, skipping the first 20 bytes of the inner IPv6 header).

For the reader's convenience, the textual representation of the pattern is used in the example instead of the binary form.

```
{
  "ietf-access-control-list:acls": {
    "acl": [
      {
        "name": "pattern-example",
        "aces": {
          "ace": [
            {
              "name": "pattern-1",
              "matches": {
                "ipv6": {
                  "protocol": 41
                },
                "ietf-acl-enh:pattern": {
                  "offset": "ietf-acl-enh:layer4",
                  "length": 20,
                  "operator": "match",
                  "pattern": "2001:db8::1"
                }
              },
              "actions": {
                "forwarding": "drop"
              }
            }
          ]
        }
      }
    ]
  }
}
```

Figure 7: Example of an ACL to Deny Encapsulated Messages with a Specific Inner Destination Address (Request Body)

B.4. VLAN Filtering

[Figure 8](#) shows an ACL example to illustrate how to apply a VLAN range filter.

```
{
  "ietf-access-control-list:acls": {
    "acl": [
      {
        "name": "VLAN_FILTER",
        "aces": {
          "ace": [
            {
              "name": "1",
              "matches": {
                "ietf-acl-enh:vlan-filter": {
                  "lower-vlan": 10,
                  "upper-vlan": 20
                }
              },
              "actions": {
                "forwarding": "ietf-access-control-list:accept"
              }
            }
          ]
        }
      }
    ]
  }
}
```

Figure 8: Example of VLAN Filter (Message Body)

B.5. I-SID Filtering

Figure 9 shows an ACL example to illustrate the I-SID range filtering.

```
{
  "ietf-access-control-list:acls": {
    "acl": [
      {
        "name": "test",
        "aces": {
          "ace": [
            {
              "name": "1",
              "matches": {
                "ietf-acl-enh:isid-filter": {
                  "lower-isid": 100,
                  "upper-isid": 200
                }
              },
              "actions": {
                "forwarding": "ietf-access-control-list:accept"
              }
            }
          ]
        }
      }
    ]
  }
}
```

Figure 9: Example I-SID Filter (Message Body)

B.6. Rate-Limit

Figure 10 shows an ACL example to rate-limit incoming SYNs during a SYN flood attack.

```
{
  "ietf-access-control-list:acls": {
    "acl": [
      {
        "name": "tcp-flags-example-with-rate-limit",
        "aces": {
          "ace": [
            {
              "name": "rate-limit-syn",
              "matches": {
                "tcp": {
                  "ietf-acl-enh:flags-bitmask": {
                    "operator": "match",
                    "bitmask": 2
                  }
                }
              },
              "actions": {
                "forwarding": "accept",
                "ietf-acl-enh:rate-limit": "20.00"
              }
            }
          ]
        }
      }
    ]
  }
}
```

Figure 10: An Example of Rate-Limiting Incoming TCP SYNs (Message Body)

Acknowledgments

Many thanks to Jon Shallow and Miguel Cros for their review and comments on this document.

Thanks to Qiufang Ma, Victor Lopez, Joe Clarke, and Mahesh Jethanandani for their comments and suggestions.

Thanks to Lou Berger for shepherding this document.

Thanks to David Black for the tsvart review, Tim Wicinski for the intdir review, Per Andersson for the yangdoctors review, Russ Housley for the genart review, and Linda Dunbar and Sean Turner for the secdir reviews.

Thanks to Erik Kline, Mike Bishop, Éric Vyncke, Roman Danyliw, and Deb Cooley for the IESG review.

The IANA-maintained modules were generated using an XSLT stylesheet from the 'iana-yang' project [[YANG-XSLT](#)].

This work is partially supported by the European Commission under Horizon 2020 Secured autonomic traffic management for a Tera of SDN flows (Teraflow) project (grant agreement number 101015857).
